Processing Ultra-Wide Band Gap Ga₂O₃

Moderator: Daniel Pennachio, Naval Research Laboratory

11:00am **EM2+CA+CPS+MS+SE+TF-WeM-13 Ga₂O₃ Polymorphs: Epitaxial Film Growth, Characterization and Contacts**, *Lisa Porter, Jingyu Tang, Kunyao Jiang, Robert Davis, Posen Tseng, Rachel Kurchin*, Carnegie Mellon University; *Luke Lyle*, Penn State Applied Research Labs; *Carlo Schettini Mejia*, Carnegie Mellon University

INVITED

The last decade has shown a dramatic increase in research on gallium oxide (Ga₂O₃) as an ultra-wide bandgap semiconductor for electronics that can operate in extreme conditions, such as high power, high temperature and radiation exposure. This presentation will focus on unique and intriguing characteristics associated with two processes that are necessary to produce Ga₂O₃-based devices: the growth of epitaxial films and the formation of ohmic and Schottky contacts. Whereas β -Ga₂O₃ is the thermodynamically stable phase, the other, metastable, phases of Ga₂O₃ can be produced as epitaxial films in either mixed-phase or pure-phase form. Our results, along with those in the literature, indicate that the phase content and other film properties strongly depend on the growth method (e.g., MOCVD, HVPE, mist CVD, etc.) and other conditions during film growth, such as precursor chemistry, flow rates, temperature, and substrate material / orientation. Our group has also conducted comprehensive studies of ohmic and Schottky contacts to β -Ga₂O₃. For reasons that are not well understood, only a few metals have been demonstrated as practical ohmic contacts to Ga₂O₃. Whereas Ti/Au contacts annealed at 400–500 °C are widely used, Cr/Au contacts annealed in a comparable temperature range also form ohmic contacts to Ga₂O₃. Controlled studies of several different elemental-metal Schottky contacts show that their electrical behavior highly depends on the particular Ga₂O₃ surface on which they're deposited; observed behavior ranges from Fermi-level pinning on the (-201) surface to near-ideal Schottky-Mott behavior on the (100) surface. Examples of the phenomena outlined above will be summarized and presented using results from high-resolution transmission electron microscopy, x-ray diffraction, and electrical measurements.

11:30am **EM2+CA+CPS+MS+SE+TF-WeM-15 Compensating Interfacial Parasitic Si Channels in β -Ga₂O₃ Thin Films Via Fe δ -doping**, *Prescott Evans, Brenton Noesges, Jian Li, Mark Gordon, Daram Ramdin, Shin Mou, Adam Neal, Thaddeus Asel*, Air Force Research Laboratory, USA

β -Ga₂O₃ is a promising material for high power applications given an ultra-wide bandgap and predicted high break down field. One challenge with β -Ga₂O₃ for lateral device architectures is the presence of undesired Si between epitaxial thin film and substrate which creates a parasitic conduction channel. This channel limits performance and can prevent device modulation. Attempts to remove this interfacial layer using etch methods have proven mostly successful. However, in plasma-assisted oxide molecular beam epitaxy (PAMBE), conventional removal efforts appear unsuccessful. Our results show interfacial Si can reaccumulate at clean β -Ga₂O₃ surfaces from various Si sources inside the MBE tool such as the Si doping effusion cell. Hence, careful growth steps must be considered to avoid Si reaccumulating onto clean β -Ga₂O₃ surfaces in PAMBE. This work presents an alternative to mitigate the influence of this Si parasitic conduction channel via Fe delta doping at the interface. We demonstrate how a thin Fe layer at the interface can compensate interfacial Si and create an interface without excess free charge. The growth methodology presented involves multiple steps to avoid Fe diffusion from the interface. We first deposit the Fe followed by a low temperature (LT) undoped buffer before depositing an Si doped channel layer at higher deposition temperatures. The LT buffer helps minimize Fe surface riding and diffusion while the increased substrate temperature during the Si doped channel improves surface roughness. Secondary ion mass spectrometry (SIMS) results show Fe only resides at the interface between substrate and LT buffer layer with Fe concentration in the LT buffer and Si doped channel below the noise floor of the instrument. Furthermore, SIMS shows a smooth transition in Si concentration from the LT buffer into the intentionally Si-doped channel region avoiding any spikes between the two layers, indicating high degree of controlled doping localization. Initial capacitance-voltage (C-V) measurements on samples with the Fe compensation show no spike in carrier concentration near the substrate interface indicating Fe is fully compensating interfacial Si. These results demonstrate a potential method to mitigate parasitic Si conduction

channels in β -Ga₂O₃. However, time-dependent C-V results show there is some capacitance transients when the sample is fully depleted. While Fe seems initially promising other compensating acceptors such as N or Mg need to be explored given this observation of capacitance transients in Fe-doped structures. Overall mitigating this parasitic interface will help improve yield and performance uniformity in fabricated devices.

11:45am **EM2+CA+CPS+MS+SE+TF-WeM-16 Investigating Metal Gate-Driven Interfacial Reactions in ALD-Grown Al₂O₃ on β -Ga₂O₃**, *Joy Roy, Adam A. Gruszecski*, The University of Texas at Dallas; *Khushabu S. Agarwal, Paolo La Torraca, Karim Cherkaoui, Paul K. Hurley*, Tyndall National Institute, University College Cork, Ireland; *Chadwin D. Young, Robert M. Wallace*, University of Texas at Dallas

β -Ga₂O₃ is a leading candidate semiconductor for next generation power electronics with the potential to outperform GaN and SiC owing to its high breakdown strength paired with low power losses.¹ Integrating a robust gate dielectric and stable oxide interface is critical in leveraging these properties of β -Ga₂O₃.² However, this cannot be achieved without also considering the gate electrodes' reactivity and their influence on oxide properties. This work explores interfacial reactions—particularly those associated with oxygen scavenging—and the resulting variations in gate oxide performance induced by Ni and Ti gate metals in Al₂O₃ on bulk (001) β -Ga₂O₃ substrates.

Interface reactions were analyzed via *in situ* X-ray photoelectron spectroscopy (XPS) in an ultrahigh vacuum (UHV) cluster system. β -Ga₂O₃ samples were scanned as-loaded, after atomic layer deposition (ALD) of ~2 nm Al₂O₃, and a third time following UHV electron beam deposition of Ni or Ti (~1 nm) to assess changes in interface chemistries. Additional chemical states in Ga₂O₃ were below the XPS detection limit after oxide and metal deposition. However, an AlO_x (sub stoichiometric) state appeared in Al core levels (2p or 2s) after introducing Ti. This, along with a TiO_x state in Ti 2p, may imply oxygen scavenging from Al₂O₃. While both metals reacted with surface organic residues from metal-organic precursors, Ti exhibits more carbide formation at the gate/dielectric interface. Additionally, MOSCAPs were fabricated with ~12 nm Al₂O₃ and 10/100 nm of either Ni/Au or Ti/Au as the gate metal for I-V and C-V characterization. Ni/Au devices showed lower frequency dispersion and over two orders of magnitude lower gate leakage in accumulation than Ti/Au samples, consistent with the XPS findings. Dielectric breakdown strength will be further studied to explore electrical stability of the oxides.

In conclusion, a fundamental understanding of gate metals' influence on interface properties is essential for precisely predicting device behavior in power electronics.
